ABSTRACT

Some oral manifestations have been observed in patients with coronavirus disease in 2019 (COVID-19). However, there is still a question about whether these lesions are due to coronavirus infection or secondary manifestations resulting from the patient’s systemic condition. Thus, this article aims to report an additional case of the oral conditions in a patient diagnosed with COVID-19. Our patient, a sixty-seven-year-old Caucasian man, tested positive to coronavirus and presented oral manifestations such as recurrent herpes simplex, candidiasis, and geographic tongue. We support the argument that some oral conditions could be secondary to the deterioration of systemic health or due to treatments for COVID-19. The present case report highlights the importance of including dentists in the intensive care unit multi-professional team to improve oral health in critical patients not only COVID-19 patients. Also, to contribute to evidence-based and decision-making in managing infectious diseases.

Key Words: COVID-19; SARS-CoV-2; Oral conditions; Recurrent herpes simplex; Candidiasis; Geographic tongue; Case Report.
INTRODUCTION

The novel coronavirus disease 2019 (COVID-19) presents an important and urgent threat to global health. The novel coronavirus was initially named 2019-nCoV and officially as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) (WHO, 2020). The lungs are the primary site of infection for COVID-19, with patients presenting symptoms ranging from mild flu-like symptoms to fulminant pneumonia and potentially lethal respiratory distress (Guan et al., 2020).

There have been some COVID-19 cases reporting oral manifestations (Chaux-Bodard et al., 2020; de Maria et al., 2020; Lechien et al., 2020; Martín Carreras-Presas et al., 2020; Putra et al., 2020). In this field, since oral health of COVID-19 patients can be affected by the infection, there is still doubt whether these manifestations could be a typical pattern resulting from the direct viral infection. Maybe, oral lesions can result from the systemic deterioration, considering the possibility of opportunistic infections and also adverse reactions of treatments. Therefore, the range of COVID-19 manifestations in the oral cavity has been considered of broad and current interest. The overall objective of this brief article was to report a relevant case of the oral manifestations in a COVID-19 patient.

CASE REPORT

On March 31st, 2020, a sixty-seven-year-old Caucasian man with a history of cruising the Brazilian coast in the past 30 days was admitted at Hospital Alvorada Brasília, Brasilia, Brazil. Ten days earlier, the patient developed respiratory symptoms and progressive dyspnea on exertion, in addition to fever and diarrhea. The patient was asked about symptoms of gustatory and olfactory dysfunction, and he reported hypogeusia. In the medical history, the patient reported coronary
disease, already revascularized, systemic hypertension, autosomal dominant polycystic kidney
disease, and kidney transplant, which led him to take immunosuppressants regularly and to use
pharmacological prophylaxis for venous pulmonary thromboembolism with Enoxaparin sodium
(Clexane® 20mg/day). A nasopharyngeal swab following reverse-transcription polymerase chain
reaction (RT-PCR) for SARS-CoV-2 RNA amplification resulted in positive. Chest computed
tomography evidenced bilateral diffuse hyperdense infiltrations in the so-called “ground glass”
pattern affecting both lungs, leading to intensive care unit (ICU) admission for supplemental O₂.
Thereafter, the patient underwent orotracheal intubation due to disease progression and respiratory
failure, and the patient was treated with Hydroxychloroquine sulfate (Reuquinol®, 400mg/day),
Ceftriaxone sodium (2g/day), and Azithromycin (Zitromax® 500mg/day) for seven days.

Due to clinical suspicion of pneumonia associated with mechanical ventilation, and
worsening of the white blood cell count, a new antibiotic regimen was started with Meropeném
(Meronem®, 1000mg, 8/8hs) and Sulfamethoxazole+Trimetropin (Bactrim®, 400mg +80mg, 1.5
ampule, 8/8hs) for 10 days. Then, the patient underwent a tracheostomy. Hemodialysis was
performed with subsequent recovery of renal function. The mechanical ventilation was maintained
with good recovery and the possibility of spontaneous breathing. Also, the patient returned to the
use of immunosuppressants and pharmacological prophylaxis for venous and pulmonary
thromboembolism with Enoxaparin sodium (Clexane® 60mg/day).

On the twenty-fourth day of hospitalization, the dentists (R.L.C.S. and R.M.P.) were called
to assess a persistent white plaque on the tongue dorsum. This lesion was previously treated by the
physicians with intravenous Fluconazole (Zoltec® 200mg/100mL, one bag a day for 10 days) and
oral nystatin (100,000 IU/mL, 8/8h, for 30 days), but no regression was observed. In addition to the
white plaque, the dentist also observed multiple pinpoint yellowish ulcers in the tongue dorsum
resembling the late stage of herpetic recurrent oral lesions (Fig. 1A). After a complete intraoral examination, no other lesions on the oral mucosa were observed, except for a nodule located in the lower lip, measuring approximately 1 cm in its largest diameter, suggestive of a reactive lesion (fibroma) that was confirmed by the patient’s pre-existence. Tongue scrape culture was performed, which was compatible with *Saccharomyces cerevisiae*. Extremely viscous saliva was observed, and biopsies were not recommended due to the patient's systemic conditions. And, cutaneous lesions were not observed during the patient's physical examination. At this time, the patient kept the antifungals and was treated with chlorhexidine digluconate (0.12%) alcohol-free mouth rinses, in addition to daily applications of 1% hydrogen peroxide. The dentist also instructed the health team on the importance of maintaining oral hygiene care.

Two weeks after the first oral examination, the white lesions on the tongue dorsum showed almost complete resolution. In a new intraoral examination, it was observed that the patient presented an asymptomatic geographic tongue classified as severe, according to the severity index recently published (Picciani et al., 2019) (Fig. 1B), associated with fissured tongue.

The patient was discharged from the ICU and in the subsequent days, there was a prompt recovery. The patient had no fever and the physician had been able to gradually decrease oxygen flow, and antibiotic therapies were discontinued. At that moment, in a hospital apartment, he was conscious, oriented, and not dependent on oxygen therapy. Also, the patient had no complaints, preserved appetite, good water consumption, good urine volume, and afebrile.

On May 14th, the patient was discharged after forty-four days of hospitalization, also the dentist only prescribed oral health care. Ten days later, the patient sent us an intraoral image where it could be observed maintenance of geographic tongue but now classified as moderate, according to the severity index recently published (Picciani et al., 2019). In addition, a slightly erythematous
area could be seen in the right palatine tonsil region, however, the patient reported being asymptomatic (Fig. 1C).

**DISCUSSION**

Current research shows that coronavirus damage to respiratory and other organs could be related to the distribution of angiotensin-converting enzyme 2 (ACE2) receptors in the human system (Zou et al. 2020). Therefore, cells with ACE2 receptor distribution may become host cells for the virus and further cause inflammatory reactions in related organs and tissues, such as the tongue mucosa and salivary glands (Xu et al. 2020). Besides, available evidence has not established an efficient and safe pharmacological agent against COVID-19 yet, and the potential ones are related to several adverse reactions, including oral lesions (de Melo Filho et al. 2012; Godinho et al., 2020; Mehra et al., 2020; National Center for Biotechnology Information, 2020). In addition, COVID-19 acute infection, along with associated therapeutic measures, could potentially contribute to negative outcomes concerning oral health, likely leading to various opportunistic fungal infections, recurrent oral herpes simplex virus (HSV-1) infection, oral unspecific ulcerations, fixed drug eruptions, dysgeusia, xerostomia linked to decreased salivary flow, ulcerations and gingivitis as a result of the impaired immune system and/or susceptible oral mucosa (Dziedzic & Wojtyczka, 2020).

The oral conditions presented by our patient and other cases already reported (Martín Carreras-Presas et al., 2020; Putra et al., 2020) supports the hypothesis that they are highly suggestive of secondary lesions resulting from the deterioration of systemic health or due to treatments for COVID-19. Even considering our hypothesis of associated conditions, the relevance of the dentist as part of the multi-disciplinary team in supporting critical patients in ICU such as COVID-19 should be highlighted. Also, dental follow up after the patient is dismissed from the
hospital must be provided. In COVID-19 patients we should consider the occurrence of some oral signs and symptoms, including dysgeusia, petechiae, candidiasis, traumatic ulcers, HSV-1 infection, geographical tongue, thrush-like ulcers, among others. Thus, the importance of the clinical dental examination of patients with infectious diseases in the ICU should be emphasized, considering the need for support, pain control, and quality of life.

**Ethical Approval and Informed Consent:** The study has been conducted in full accordance with ethical principles (Declaration of Helsinki), and written informed consent was obtained from the patient.

**Conflicts of Interest:** None to declare.

**Funding:** Decanato de Pesquisa e Inovação, Universidade de Brasília, EDITAL DPI-UnB Nº 04/2019 – (ENSG grant 33902001).

**Author Contributions:** ENSG, JAS and AGCN: Conceptualization, Study design, Literature research, Writing-original draft. RLCS, RMP and ACC: Clinical studies, Treat the patient, Data acquisition, Writing-review. ARSS: Validation, Writing-review.
